Evolutionsgenetik

Evolutionary genetics is the broad field of studies that resulted from the integration of genetics and Darwinian evolution, called the 'modern synthesis' (Huxley 1942), achieved through the theoretical works of R. A. Fisher, S. Wright, and J. B. S. Haldane and the conceptual works and influential writings of J. Huxley, T. Dobzhansky, and H.J. Muller.

Evolution is the process by which populations of organisms change over generations. Genetic variations underlie these changes. Genetic variations can arise from gene mutations or from genetic recombination (a normal process in which genetic material is rearranged as a cell is getting ready to divide).

Zusammenfassung. Die Evolutionstheorie war die führende biologische Theorie des 19. Jahrhunderts. In unserem Jahrhundert ist sie durch die Genetik ergänzt worden (Vorlesung 1); beide Theorien zusammen ergeben ein in großen Zügen vollständiges Bild darüber, wie sich die Vielfalt des Lebens auf diesem Planeten entwickelt hat.

Human evolutionary genetics studies how one human genome differs from another human genome, the evolutionary past that gave rise to the human genome, and its current effects. Differences between genomes have anthropological, medical, historical and forensic implications and applications. Genetic data can provide important insights into human evolution

Dzierzon postulated that male bees derive from unfertilized eggs, while females come from fertilized eggs. Male bees possess one set of chromosomes, while the females have two sets, a phenomenon known as haplodiploidy that was later confirmed with the development of high-quality microscopes.

The Department of Evolutionary Genetics studies the genetic history of humans, apes and other organisms. We are interested in both the forces that affect the genome directly, such as mutation and recombination, and in the effects of selection and population history.

Die Populationsgenetik ist der Zweig der Genetik, der Vererbungsvorgänge innerhalb biologischer Populationen untersucht. Sie ermittelt die relative Häufigkeit homologer Gene in Populationen (Genfrequenz) und erforscht deren Veränderung unter dem Einfluss von Mutation, Selektion, zufälliger Gendrift, der Separation von Teilpopulationen und dem Genfluss zwischen Populationen.
